Abstract — eLearning kind of education is stirring up all the disciplines in the academic circles, especially since it provides an access to educational areas that are uneasy and traditionally imperson, such as Engineering. Even though it had an outbreak in some of the most prestigious American universities, eLearning has been a reality in Spain for some years now, changing educational and teaching habits. To ensure a proper education is not an easy task with it comes to engineering fields, therefore this article shows an update on the works developed on this issue and the technologies they used. In this report it is given a perspective of the intimate relationship between the eLearning method of learning and the studies of Engineering in Spain, through the TIC development and the current educational legislation. In this regard, teaching examples are given on several subjects of different engineering studies, emphasizing the good results obtained in the abovementioned experiences. Below here is an evaluation on the results obtained in the analyzed studies.

Keywords — eLearning, engineering, competencies, evaluation.

I. INTRODUCTION

ROYAL Decree 1393/2007 establishes the new regulation on official university educations. Through this decree, the Spanish university system is integrated in the European Higher Education Area (EHEA). In accordance to this new model, there has been a major swift, going from a teaching model based in the transmission of knowledge directly from the professor, to a model based on acquiring different competencies and the alumni learning process. Engineering studies, both from a grade and postgraduate point of view, have not been an exception.

Concisely, a competency, in the engineering environment, refers to the activities the engineer must be able to perform, using the information, skills and tools required to accomplish his professional practice [1]. This way, an education based on competencies is referred basically to expected and visible performances, meaning analysis, synthesis and evaluation.

The necessary learning process is not oblivious to the present technological changes, the use of TIC has lead to a big leap in evolution of distance learning, creating the eLearning method of education. eLearning provides the opportunity to create virtual learning environments focused on the student, as EHEA demands. The aim of these virtual learning environments is to move the emphasis from the teaching to the learning [2].

These scenarios are characterized by being basically interactive, efficient, distributed and easily accessible. According Khan, quoted by Boneu [3], an eLearning scenario must consider eight facts: instructional design, educational model, technology, interface development, evaluation, management, support and use ethics. The platform in which the eLearning is developed is the software server responsible for the users management, courses management and communication services. These platforms are not isolated systems, given that they can rely on tools developed by third parties or on integrations developed by the designers or administrators.

Fig.1. General Diagram of Contents Generation

eLearning can enhance some of the competencies that an engineer must develop, such as: identification, formulation and resolution of problems, the ability to design experiments or the ability to apply math, among others.

The specifications development, standard and tools regarding cognitive systems, ontologies and semantic maps are also helping in the formative systems enhancement.

In essence, the systems are based in showing some contents after receiving some request from the user. To this effect, the knowledge basis provides all the available information on this issue and some restrictions will select the definitive contents to show. Work on Intelligent Educational Systems (IESs) is traditionally divided into two main paradigms [4]: Intelligent Tutoring Systems (ITSs) [5] [6] and Adaptive Hypermedia Systems (AHSs) [7] [8].
According Caravantes and Galán [9], the essential part of the teaching-learning model is the educational domain, which is responsible for the stimuli generated toward the student to properly modify his cognitive state. All intelligent educational systems incorporate an educational domain that determines its scope and the process effectiveness. Usually the educational domain is divided into two parts: one represents the target knowledge of the learning process and is called domain model, and the other defines rules or procedures governing the process and is called the pedagogical/adaptive/operational model.

Teachers use the educational knowledge of a particular domain together with a meta-knowledge that encodes pedagogical skills for process controlling. This pedagogical knowledge represents instructional principles such as positive reinforcement, variability, action, etc., that facilitate the proper selection and sequencing of contents. It is a type of procedural knowledge based on Pedagogical Regulators (PRs) that controls the process, reading information from the emotional, characteristic and instructional domains. Common IESs implement an explicit pedagogical knowledge just as expert systems do using PRs called logical rules. However, there are other valid implicit representations such as neural networks, in which the PRs are called nodes, artificial neurons, and so on.

Learning content specifications like ADL-SCORM [10] or IMS-CC [11] are based on independent and interchangeable objects or packages that encode one or more ways to teach-learn something.

Distance learning has usually made available to the student a set of continuous learning resources (documents, presentations, videos, animations and simulations) and discrete resources (texts, graphics, links and images) [12]. Resources are located at the lower material level of the educational knowledge structure to interact with the student to transfer knowledge. Educational resources are increasingly specified by soft links [13] that allow them to be searched, filtered and selected from large and dynamic repositories using metadata such as type (exercise, questionnaire, diagram, graph, table, text...), format, language, difficulty, etc. (see IEEE-LOM).

In this article, we will go through some of the experiences performed in the engineering area from the eLearning point of view, since just from the beginning eLearning and engineering have got along very well. Due to this connection, engineering learning becomes a higher quality learning, therefore it provides engineering a wider coverage regarding its education and extension [14].
eLearning education in order to make sense out of engineering eLearning education. Therefore, the first works are somehow recent, as shown in some of the most important works, summarized below.

One of the first approaches in literature we can find was in 2000. In that year, there were already many American universities that would offer a wide range of courses with the eLearning teaching method [15], proving that, right from the start, eLearning was meant to become one of the strongest lines of high education.

Databases knowledge is one of the paramount subjects in the high courses of computer engineering. Back in 2006, and through the use of eLearning platforms, it was achieved not only to increase the motivations but to improve the academic results of the alumni in the Technical Engineering in Computer Managements and Systems in Gerona University [16]. The most relevant achievement of this study was the tool that auto corrects the exercises related to the subject. This tool allowed the professor to acknowledge the learning level of the students and realize their possible deficiencies. Also, there are significant gains for the students, since the passing rate increased around a 9%. This increase might be caused by a sizeable boost of students that have taken on tutorial classes on the course.

In courses like “Databases” and “Business and Commercial Management Techniques”, the auto correcting system had a great acceptance both within alumni and teachers, saving the later a significant work load: having to correct several exercises [17].

A very important aspect of this learning method is all that is related with the use and development of tools that will allow us to evaluate the assignments of the students in every subject automatically. In other words, a field that refers to the application of the different information and communication technologies in order to establish learning platforms and environments to make to evaluation of the alumni easier.

This way, the Computer Based Assessment (CBA) represents one of the eLearning technologies, distinguished by the automation of every teaching/learning feature of the student, integrating advanced functions held jointly, i.e., correcting databases structure diagrams and related consults [18]. With this CBA, there is an interaction between teacher and student all along the evaluation process. In this process, the turn in of the course exercises, its correction and the feedback generated is performed by the system automatically.

Put this into practice, CBA has been used in educational subjects of the science/technical area, mainly in test or multiple choice questions, with a limited scenarios feedback. The reason of these limitations is the disaffection toward these kinds of questions, since they can be perceived as distant and only acceptable in some low cognitive leveled tasks, which require fixed answers.

With this tool (CBA), the author scored better academic results and a higher satisfaction on the environment developed in students of the Databases subject of the Technical Computer Management Engineer of the Gerona University.

One of the tools that contributes to improve the learning process in multimedia environments are the Learning Objects, which are digital resources based on the Web, whose main feature is they can be used and reused to support the learning. A Learning Object (LO) is the minimal learning unit that has sense by itself, regardless of the context. Furthermore, it is a unit with an educational content and reusable in its digital format. Since this format must be standardized, it can be reused in different platforms, ensuring its reusability and usefulness [19]. Among these digital resources you can incorporate images, videos or pre-recorded audios, small text pieces, animations, little Web apps or even entire Web sites combining texts, images and other communication media.

One good example of the reusability and usefulness of the Learning Objects is the one performed on the Industrial Engineer School of Vigo University. Through this action, it was expected to encourage and motivate the engineering learning of the alumni, even though it can be conducted in any other discipline [20]. The authors designed a learning pill (very short course the summarizes the main concepts of the subject) in order to use it as a tool the students must use before the master lectures, but due to the specific features of the learning pills, they can be reached and used at any time and any place, thanks to their free access. The learning pill was effectively used by the whole alumni and it was verified that it was used worldwide.

The incorporation of multimedia technology and eLearning education has been applied equally to the Project Direction learning [21]. These authors instituted the eLearning technology in the “Projects” subject on the Industrial Engineering degree at Escuela Politécnica Superior de Ingeniería in Gijón. In order to achieve this, in this occasion it was selected a platform different from the traditional ones, such as Moodle. In this case, Microsoft Sharepoint was used, a specific project management tool, favoring the approach of the teacher’s work towards the professional environment. The experience, besides enhancing the cooperative work between students, contributed to preparing the alumni towards the analysis, evaluation and alternatives choice, leading them to an educated decision making, something of paramount importance in their future engineering works. Nowadays, the eLearning method is widely spread in Projects Direction and Management and programs exist in most of the Spanish universities.

In engineering teaching, on-line methodologies have also been applied for evaluation and formation in generic competences. In the Technical Computer Engineering School of the Universidad Politécnica de Madrid it has been developed a competence approach for the “Telecommunications History” and “Telecommunications Policy for the Information Society” subjects, which were given through the Moodle platform. It is worth mentioning that the chosen teaching method was eLearning which, unlike eLearning, it combines online contents with in-person given contents. The results, evaluated through an online survey to the alumni, were highly satisfactory, pointing out several technical aspects, mainly the simplicity in the use of the Moodle platform [22].

The eLearning app can be used in any kind of subject, being the Logic subject of Computer Engineering both a particular
III. Conclusion

In every experience analyzed in the present article is possible to detect the efficiency of the eLearning educational method in all the Engineering areas. In the abovementioned projects and their corresponding evaluations, is obvious the good results scored and the satisfaction of the students. The alumni feedback is very important for every learning method, through a satisfaction survey or test, but especially in this kind of method, since the student judges only the knowledge he has acquired, withdrawing any personal relationship he may have with his tutor, which can get even closer that in-person classes.

When it comes to eLearning education, the behavior of the system relies mainly in two factors: architecture and contents. In every cases previously analyzed, both factors are combined. The potential of these systems increases remarkably when Artificial Intelligence techniques are integrated, leading the system to a teacher-cognitive system combination that ensures not only the contents transmission but the proper choice of content within the wide knowledge database, supported by teaching techniques that permit an effective contents transmission as well as a certain knowledge acquisition. Therefore it seems to be proof enough to state the validity of eLearning when it regards to engineering, as The American Accreditation Board for Engineering and Technology (ABET) claims [27]. Accordingly, not only the students score better results, but there is a possible chance to widely extend the education while cutting expenses, two important features when it comes to practice subjects to perform in laboratories.

However, there is a certain lack of more specific experiences, with a better educational design, and a lack of experiences that affect the paramount subjects of every engineering university title, both degree and masters. Besides, it would be convenient to expand the evaluation to teachers and apply a more severe criteria to evaluate de possible academic scores improvement, establishing the criteria required in order to ensure the students the correct acquisition of competencies.

Also it would be desirable a future research on the feelings of the student towards his presence and involvement in certain subjects and the improvements this might bring, being this an aspect where is pivotal the development and application of every multimedia technology available.
