ABSTRACT

There is a lack of motivation in children and adolescents to do physical exercise and at the same time a worldwide obesity epidemic. Gamification and active videogames can be used to increase the motivation of young people, promoting healthy habits. In this work we explore different studies on active videogames, eSports and gamification applied to physical exercise and health promotion. Main findings include positive effects in a reduction in body weight and in the promotion to continue performing of physical exercise. It also contributes to increase the motivation in children and adolescents to practice exercise. The personalization of user experience and emerging technologies (big data, wearables, smart technologies, etc.) are presented as promising opportunities to keep the engagement in game-based program and gamification of physical exercise.

I. INTRODUCTION

In the school or outside, physical exercise (PE) is considered a positive element and widely as a fun, engaging and social activity. Inside schools, there is a curricular formal PE, named Physical Education, which main goals is to develop motor skills, knowledge and healthy behaviors. Outside schools, PE can have many non-formal ways: fitness, sports, dancing, etc. But, many times, the PE lessons in school are the main PE that young people and children have [1]. Physical and active games can attract children and young people to have a regular PE and in this way, to promote healthy habits and wellbeing.

PE can be gamified or transformed into an active game if we consider that any process that satisfies the following premises can be gamified: “the activity can be learned; the user actions can be measured, and the feedbacks are timely delivered to the user” [2].

In the creation of active games, as in other types, designers must take into account fundamental elements. These game elements can be classified in many diverse ways, for example, as:

- Mechanic, story, aesthetics, and technology [3].
- Interfaces, rules, entity manipulations and goals [4].
- Mechanics, dynamics and aesthetics [5].
- Mechanics and dynamics [6].
- Dynamics, mechanics and components [7], organized in a pyramid structure, according if the element is conceptual or tactical.

Although, the most common elements associated to gamification are points, badges and leader-boards (PBL), there are diverse frameworks to design or gamify systems with a variety of elements related to the intrinsic and extrinsic motivation of user [8, 9]. These elements allow the design of personalized gamified experiences according to the user preferences.

In this paper we perform a literature review to extract the elements of games and gamification used for PE and their effectiveness.

II. STUDIES ABOUT GAMES AND GAMIFICATION FOR PE

In the literature we can find several studies about games and PE related with the energy expenditure in educational programs carried out in schools combined with children’s leisure time [10]. Main findings include that these kind of physical educative programs in schools increase the motivation of children and adolescents to continue performing physical exercise [11]. But, not all physical activity impacts in the reduction of body weight, because it depends on the frequency, duration and intensity of the activity [12]. For example, in the study carried out in [13] related to the dancing game, it was found that the cardiorespiratory answer was comparable to an aerobic dance of medium to high intensity [13].

Regarding the motivation to PE, some studies conclude that is better to encourage children participating in team rather than in individual sports [14]. Also, in other study on a group of overweight children and adolescents using an exergame (Dance Dance Revolution of Konami) as a routine physical activity, found that the game was not enough to motivate them to participate. Then, to increase participation researchers encouraged cooperative play, increased the musical variety and included a competitive mode in the activities [15]. Besides, a dancing videogame used in children’s homes was evaluated while they were playing weekly in group. Results showed that the motivation and participation increased due to the group sessions [16].

Moreover, the use of active videogames has positive effects promoting an active lifestyle. A study compared the energy expenditure (EE) required by a sedentary game and two active videogames, finding that the non-active game increased 22% the EE, in contrast to active games, that increased 108% in the case of torso’s movements and 172% in the case of dancing. The same study found that non-obese children had lower EE when playing the dancing video game than...
obese children [17]. Other studies about EE with active games found that the EE was significantly higher in these kind of games than with conventional videogame [18], [19]. Similar findings of other study showed an increase over the baseline of between 120% and 140% in the EE and the energy consumed playing active games, similar when the participant did other PE (walk, jogging, swimming) [20]. Besides, in other study the calories consumed at rest, while watching television and while walking was measured in children and compared with the calories burned when playing active videogames. The results revealed that children burned the same amount of calories when they walked moderately and three times more than while resting [21].

Although positive effects were found in several studies on the EE with active videogames, PE and sports cannot be replaced. As we mentioned above, EE depends on the intensity, duration and frequency of the activity and only a few active videogames allow performing PE with moderate intensity [22].

Several studies describe the effective use of technologies with children in the promotion of healthy habits [23]. Some gaming platforms includes body movement as an interactive element that can be used for PE [24]. Also, outdoor PE are favored by smartphones supporting different sensors tracking biometrics and allowing augmented reality activities [25]. Other technology is the Playware based on the use of sensors, actuators, hardware and software for playgrounds [26]. In Playgrounds, some game elements like social interaction, simplicity, challenge, goals, and feedback should be considered [27]. Playgrounds can be used to spatial cognitive development, considering multiple perspectives, zooming in and out, distances, experiencing movement or finding visual cues [28].

Other game elements that should be considered in the design of educative videogames in general and for active videogames in particular are collaboration and social aspects [29]. A set of theoretical elements for the design of educational videogames were proposed [30] and for monitoring and evaluating educational videogames [31].
the game show the potential of gamification as an emergent learning strategy in PE because increase the motivation and promote the healthy habits in the students.

Other relevant project on gamification in PE is “ExpandeEF” or Expanded Physical Education, work developed by Lucia Quintero (2017) [43]. ExpandeEF was applied during one academic course with students of the second year in a high school of Tenerife (Canary Islands, Spain). Quintero (2017) used not only gamification strategies to design the experience, but emergent didactic methodologies such as mobile learning, flipped classroom or service-learning was applied (Fig. 1).

Also, several related projects have been developed by our research group, such as:

- **VIDEM** (Developing healthy habits and physical education through active educational games for hospitalised children and adolescents) funded by the Ministry of Science and Innovation, Ref. EDU 2010-10010, had the main goal of developing healthy habits through motor games and active video games in hospital classrooms. Among the objectives of the project, there are: a) Designing a model of educational intervention through physical exercise and ICT. The exercise is the transversal educational strategy, related attitudes and communicative values for integration of minors; b) Evaluating the influence of physical activity with learning games and motor play in learning healthy habits. Besides, training interventions and effectiveness of game models and tools applied are valued. In this context, it has been made and validated an integrated educational program formed by motor games and active videogames for the development of healthy lifestyles at a primary school [32]. URL: http://videm.es/

- **SALUD-in (Platform for Interactive Virtual Rehabilitation with Physical Social Games for Health and Techniques of Natural Interaction)** Ref PROID20100218, funded by the Canarian Agency for Research, Innovation and Information Society. This interactive platform, aimed at hospitalised children, allow the virtual-based rehabilitation based on physical social games for health and natural interaction techniques. It is based on multiplayer games, with games designed for physical and cognitive rehabilitation, a motion
capture system and biomedical data based on a low cost system (Kinect sensor and wearables devices). In this project TANGO:H (Tangible Goals platform) was created (Fig. 2). TANGO:H is a platform for hospitalized children with functional diversity developed by the Technological and Renewable Energy Institute (ITER) and the Interaction, Technology and Education Research Group (i-TED) of the University of La Laguna. Further it comprises a clinical management system and remote monitoring of rehabilitation exercises and medical records of patients. URL: http://saludin.es/

- Zombies, Run!: is a mobile game for running in which players have to run away from zombies. Then, while players run, stories are narrated, random sprinting to avoid zombies are launched. Players can collect items and be punctuated in personal music playlists. URL: https://zombiesrungame.com/
- Fitocracy: In this app, users work on exercise goals in group/community, and, also, can have a personal coach to keep motivated in fitness and nutrition. URL: https://www.fitocracy.com/
- VirZoom: this technology combines Virtual Reality (FR) and Fitness Technology. VirZOOM is a static bicycle connected to VR games. For example, the user can live different virtual experiences: power a horse in a race, a tank in battle, a fire-breathing dragon through mountains. URL: http://virzoom.com/

V. TRENDS IN GAMIFICATION AND GAMES FOR PE

A. Personalization

People have different ways to get fun. So, the research has identified different player types and motivations to play. Bartle (1996) [45] identified four player types: killer, achiever, socializer, and explorer. Regarding the motivations, Lazzaro (2004) [46] detected four motivational factors for playing games: hard fun, easy fun, altered state, and state and people factor, and Yee (2006) [47] identified three main motivation components: achievement, social and immersion. So, the student model must represent the way people play, and the types of players. The personalization of game elements in the system [48] should take into account the forms of adaptation proposed by Kobsa et al. (1999) [49]: to user data, to usage data and to environment data. Besides, a typology of engaged behaviors to determine if a player is engaged or not has been proposed by Bouvier et al. (2013) [50]. Some research can help to understand the influence of environment data. For example, Cheng (2011) [51] tried to find the good moments to play at work.

Therefore, in gamification it is important to know how to motivate a particular and different person at the right moment using different types of motivations [52]. Thus, it is possible uses gamification strategies based on intrinsic motivation (inherent in the person, taken for its own sake or interest, for example, status, power, access to certain skills, or to contribute to a common good) or in extrinsic motivation (outside the person, made for reward or feedback). Social strategies can be used to, for example, to compete, to collaborate or to compare achievements. In social games, there are collective mechanical equipment (projects, group scores, etc.) and other mechanical applied to the individual (motivation, positive reinforcement, etc.) [53].

Adaptation and personalization are concepts closely related and similar, which have a mutual goal: to offer a closer user experience by offering content close to the user, personalized to your interests and looking for increasing fidelity and satisfaction [53]. To perform this adaptation / personalization, the basic elements are: to define the user profile, to define the content and functionality that you want to adapt, and to define the interface elements that allow this adaptation / personalization. Personalization allows the adaptation of system through different techniques, such as content filtering or rule-based filtering, to infer the user’s needs and preferences [54]. For personalization / adaptation of a gamified system, we must think about what are the features that make the system fun and if the system can work with or without these gamified features. We must also think about how these features relate to gamified different user profiles. Moreover, we must also consider whether the system can work independently to gamification without affecting the core functionality, which in our case is learning. For example, a leaderboard can be activated for the most competitive users, while not for others like introspective or special needs users. For the adaptation / personalization experience, the
gamification engine must decide when and how specific and general features will be activated, taking into account: a) the student model (consisting of the user profile or static information and user history or dynamic information, and b) contextual information.

The static part of the student model or profile contains data such as age, gender, administrative information, learning style, type of player and preferences. Identifying the type and player preferences will increase the student motivation. The dynamics of the model student or history contains information of student interaction with the learning system and the state of their learning. However, a gamified system must also incorporate the trace of student interaction with the system for activation or deactivation of the functionality of gamification to increase the degree of engagement. Moreover, contextual information is essential in a gamification engine. The students can perform the activities from school, work or in their free time, in the classroom with their peers and with the teacher, or remotely. Student can also do the activities from a tablet, a mobile device, a laptop or desktop computer. All these contextual characteristics affect the gamified experience and the gamification engine must be able to adapt the features to different contexts. For example, if the activity is carried out in the classroom with teacher assistance, the chat cannot be very useful.

According to Gadiyar (2014) [55] “many gamification initiatives use points, badges and leaderboards as a way to motivate and incent participants to alter their behavior and use analytics to measure and monitor users’ actions and social components to increase the user motivation”, but, most of them fail to keep the user involved over the long term. The proposed solution for this problem is the personalization of the entire gamification process.

Gamification techniques should try to understand users, their personality, feelings, behaviors and actions. Big data [56], behavioral insights and elements of psychology can be used in gamification to provide a better end-user experience. Thus, in a gamification experience, every feedback, message or response should relate to user characteristics and situation properly. Typical gamification approaches, includes PBL, Levels, Feedback, Reward and Recognition techniques. The social gamification includes social media, communities, Web 2.0 elements, and big data analytics. Next generation of gamification systems, includes the elements for a personalized and contextual experience, such as: behavior-based frameworks, mental models, neuroscience and big data analytics.

B. Technology for Gamification and Games for PE

Technology plays a central role in the lives of today’s children and young people. So, the use of new technologies, apps and devices into schools, could offer more engaging physical activities and healthier lives to students. Technology should be the core of engagement strategies in PE.

Lister et al (2014) [57] establish that apps “represent a promising opportunity for getting people active and have received considerable attention but this has been at the expense of in-depth analysis of effectiveness” and if the applications are not developed properly, “they will end up in a common technology cycle of hype with the users’ feelings of failure and frustration on technology”. To promote positive and active user experience in apps, many apps uses gamification, but they only use the most convenient game elements and did not use the full potential of gamification to create a success gaming experience. So, Lister et al (2014) [57] have conducted an analysis of 132 most popular apps in markets and seems to agree with this criticism. Moreover, the authors studied if the apps addressed correctly the motivational components to produce a behavior. They found the apps ignore the individual ability to perform the behavior, being this the main issue to achieve long-term behavioral change. So, digital rewards like badges or points may not produce a long-term behavioral change. We believe that apps have potential in physical education, but the design of these apps needs put attention in to achieve a sustained change in behavior.

According to a report on active life style in young people, it is found that “today’s children and adolescents live sedentary lives full of computers, video games and television”[58]. But, certain technology (i.e. wearables, smartphones) that can encourage children to perform outdoor exercise. In this sense, some organizations like Youth Sports Trust, highlighting “the need to include wearable technology and gamification in physical education classes in schools” [59]. Furthermore, they said “in order to get children active from a young age, a more holistic approach to PE is needed, one which integrates technology and the delivery of a seamless, intuitive and digitally enhanced form of physical activity” [58]. Therefore, smart textiles can be introduced in the schools, as PE uniforms, and can take an important role in PE. For example, there are biosignal-monitoring underlayers produced by Athos, which read muscle effort, heart and breathing rates, analyses this information and push recommendations through mobile devices [58].

But tracked data on the activities and statistical information cannot be enough to transform this data into knowledge, skills, attitudes and behaviors [59], motivating and enhancing physical activity. Coaching support in physical activity can be an important key of success in PE. Moreover, school PE teachers will need skills and resources to offer a diverse set of PE activities focused on health, fitness and emotional wellbeing, and supported by technologies. Digital literacy should start at early ages and PE teachers must be put attention at this area. To use effectively technologies teachers requires a specific knowledge, but most primary school teachers tend to be generalists. And, to integrate the technology with the PE in a transparent and intuitive way it is needed to have a holistic approach.

VI. Conclusions

In this paper we presented a review about different studies on games and gamification applied to physical exercise, specially focused on the promotion healthy habits. We also present a review about the concept of “eSport” and its relationship with physical exercise and some considerations to be include in physical education programs. We found that many studies on active games or gamified physical exercise has been focused on energy expenditure and motivation.

Although, we found several studies and related project about how to use interactive technologies to promote healthy habits, most of games and gamified programs fail to keep the user involved over the long term. So, we believe that providing a more personalized experience can solve the problem of the engagement in long term. Personalization and emerging technologies (big data, wearables, smart technologies, etc.) based games and gamification for physical activity promising opportunity for getting people active.

Finally, we note that active videogames and gamification can be used in educational programs to increase the motivation of children and adolescents in physical exercise. In this sense, the nursing profession can play a fundamental role in health education. So, the educational programs to promote physical exercise and healthy habits should be designed and developed from the Primary Health Attention Centers and, also, in schools. And, the introduction of gamification into these educational programs (i.e. PROVITAO), can improve the quality of life of children who suffer from childhood obesity thanks to the acquisition of healthy habits.
